ACM International Collegiate Programming Contest
1998 East Central Regional Contest
University of Waterloo
November 14, 1998

Sponsored by IBM

Rules:

1. All questions require you to read the test data from standard input and write results to standard output. You cannot use files for input or output.
   - No whitespace should appear at the end of a line, and all lines should be terminated with a new-line.
   - Tabs should never be used.
   - Output must correspond *exactly* to the provided sample output, including (mis)spelling and spacing. Multiple spaces will not be used in any of the judges' output, except where expressly stated.
2. All programs will be re-compiled prior to testing with the judges' data.
3. Non-standard libraries cannot be used in your solutions. Neither can some standard libraries, such as the Standard Template Library (STL) and C++ string libraries.
4. Programming style is not considered in this contest. You are free to code in whatever style you prefer. Documentation is not required.
5. All communication with the judges will be handled by the submit command.
6. Each process is given 5 CPU seconds and 16 MB of memory to run.
7. The allowed programming languages are C, C++, and Pascal.
8. Judges' decisions are to be considered final. No cheating will be tolerated.
9. There are **eight** questions to be completed in **five hours**.

Problem A: Keeps Going and Going and ...

Lazy functional languages like Haskell and Miranda support features that are not found in other programming languages, including infinite lists. Consider the following simple (and useful) recursive declaration:

```
letrec
  count n = cons n (count (n+1))
in
  count 0
```

The function `cons` *cons*tructs lists, so the above declaration creates the following structure:

```
  cons 0 (count 1)
= cons 0 (cons 1 (count 2))
= cons 0 (cons 1 (cons 2 ...))
= [0,1,2,...]
```

Lazy languages can do this because they only evaluate expressions that are actually used. If a program creates an infinite list and only looks at items 2 and 3 in it, the values in positions 0 and 1 are never evaluated and the list structure is only evaluated so far as the fourth node.

It is also possible to use more than one function to build an infinite list. Here is a declaration that creates the list `["even","odd","even",...]`:

```
letrec
  even = cons "even" odd
  odd = cons "odd" even
in
  even
```

There are also functions that manipulate infinite lists. The functions `take` and `drop` can be used to remove elements from the start of the list, returning the (removed) front elements or the remainder of the list, respectively. Another useful function is `zip`, which combines two lists like the slider on a zipper combines the teeth. For example,

```
zip (count 0) (count 10) = [0,10,1,11,2,12,...]
```

Your task is to implement a subset of this functionality.

Input

The first line of input consists of two positive integers, n and m. n is the number of declarations to follow and m is the number of test cases.

Each declaration takes the form *name* `=` *expr*. There are two forms for *expr*: `zip` *name1 name2* and $x_0\ x_1\ \ldots\ x_i$ *name3*. In the first case, *name* is the result of zipping *name1* and *name2* together. The other case defines the first $i+1$ non-negative integers in the list *name* (where i is at least 0) and *name3* is the name of the list that continues it (mandatory—all lists will be infinite).

The test cases take the form *name* s e, where s and e are non-negative integers, $s \leq e$ and $e - s < 250$.

No line of input will be longer than 80 characters. Names consist of a single capital letter.

Output

For each test case, print the integers in positions s to e of the list *name*. List elements are numbered starting with 0.

Sample Input

```
5 3
S = 4 3 2 1 A
O = 1 O
E = 0 E
A = zip E O
Z = zip Z S
A 43455436 43455438
S 2 5
Z 1 10
```

Sample Output

```
0 1 0
2 1 0 1
4 4 3 4 2 3 1 4 0 2
```

Problem B: Scheduling Lectures

You are teaching a course and must cover n ($1 \leq n \leq 1000$) topics. The length of each lecture is L ($1 \leq L \leq 500$) minutes. The topics require $t_1, t_2, \ldots, t_n$ ($1 \leq t_i \leq L$) minutes each. For each topic, you must decide in which lecture it should be covered. There are two scheduling restrictions:

1. Each topic must be covered in a single lecture. It cannot be divided into two lectures. This reduces discontinuity between lectures.
2. Topic i must be covered before topic $i+1$ for all $1 \leq i < n$. Otherwise, students may not have the prerequisites to understand topic $i+1$.

With the above restrictions, it is sometimes necessary to have free time at the end of a lecture. If the amount of free time is at most 10 minutes, the students will be happy to leave early. However, if the amount of free time is more, they would feel that their tuition fees are wasted. Therefore, we will model the dissatisfaction index (DI) of a lecture by the formula:

$$DI = \begin{cases} 0 & \text{if } t = 0, \\ -C & \text{if } 1 \leq t \leq 10, \\ (t-10)^2 & \text{otherwise,} \end{cases}$$

where C is a positive integer, and t is the amount of free time at the end of a lecture. The total dissatisfaction index is the sum of the DI for each lecture.

For this problem, you must find the minimum number of lectures that is needed to satisfy the above constraints. If there are multiple lecture schedules with the minimum number of lectures, also minimize the total dissatisfaction index.

Input

The input consists of a number of cases. The first line of each case contains the integer n, or 0 if there are no more cases. The next line contains the integers L and C. These are followed by n integers $t_1, t_2, \ldots, t_n$.

Output

For each case, print the case number, the minimum number of lectures used, and the total dissatisfaction index for the corresponding lecture schedule on three separate lines. Output a blank line between cases.

Sample Input

```
6
30 15
10
10
10
10
10
10
10
120 10
80
80
10
50
30
20
40
30
120
100
0
```

Sample Output

```
Case 1:

Minimum number of lectures: 2
Total dissatisfaction index: 0

Case 2:

Minimum number of lectures: 6
Total dissatisfaction index: 2700
```

Problem C: Counterfeit Dollar

Sally Jones has a dozen Voyageur silver dollars. However, only eleven of the coins are true silver dollars; one coin is counterfeit even though its color and size make it indistinguishable from the real silver dollars. The counterfeit coin has a different weight from the other coins but Sally does not know if it is heavier or lighter than the real coins.

Happily, Sally has a friend who loans her a very accurate balance scale. The friend will permit Sally three weighings to find the counterfeit coin. For instance, if Sally weighs two coins against each other and the scales balance then she knows these two coins are true. Now if Sally weighs one of the true coins against a third coin and the scales do not balance then Sally knows the third coin is counterfeit and she can tell whether it is light or heavy depending on whether the balance on which it is placed goes up or down, respectively.

By choosing her weighings carefully, Sally is able to ensure that she will find the counterfeit coin with exactly three weighings.

Input

The first line of input is an integer n ($n > 0$) specifying the number of cases to follow. Each case consists of three lines of input, one for each weighing. Sally has identified each of the coins with the letters A–L. Information on a weighing will be given by two strings of letters and then one of the words "up", "down", or "even". The first string of letters will represent the coins on the left balance; the second string, the coins on the right balance. (Sally will always place the same number of coins on the right balance as on the left balance.) The word in the third position will tell whether the right side of the balance goes up, down, or remains even.

Output

For each case, the output will identify the counterfeit coin by its letter and tell whether it is heavy or light. The solution will always be uniquely determined.

Sample Input

```
1
ABCD EFGH even
ABCI EFJK up
ABIJ EFGH even
```

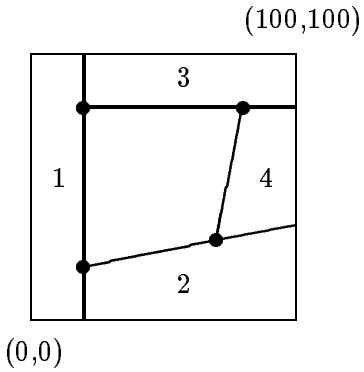
Sample Output

```
K is the counterfeit coin and it is light.
```

Problem D: Metal Cutting

In order to build a ship to travel to Eindhoven, The Netherlands, various sheet metal parts have to be cut from rectangular pieces of sheet metal. Each part is a convex polygon with at most 8 vertices. Each rectangular piece of sheet metal has width n and height m, so that the four corners of the sheet can be specified by the Cartesian coordinates $(0,0), (0,m), (n,m)$, and $(n,0)$ in clockwise order. The cutting machine available can make only straight-line cuts completely through the metal. That is, it cannot cut halfway through the sheet, turn, and then cut some more. You are asked to write a program to determine the minimum total length of cuts this machine has to make in order to cut out the polygon.

For example, if $n = m = 100$, and the polygon has vertices $(80,80), (70,30), (20,20)$, and $(20,80)$, the following diagram shows the optimal cut (the thick lines). The numbers show the order in which the cuts are made.



Input

The first line of input contains the two integers n and m where $0 < n, m \leq 500$. The next line contains p, the number of vertices in the polygon, where $3 \leq p \leq 8$. Each of the next p lines contains two integers x and y where $0 < x < n$ and $0 < y < m$, specifying the vertices of the polygon. The vertices are listed in clockwise order. You may assume that the polygon does not intersect itself, and that no three consecutive vertices are colinear.

Output

Print the minimum total length of cuts required to cut out the given polygon, accurate to 3 decimal places.

Sample Input

```
100 100
4
80 80
```

```
70 30
20 20
20 80
```

Sample Output

```
Minimum total length = 312.575
```

Problem E: Street Directions

According to the Automobile Collision Monitor (ACM), most fatal traffic accidents occur on two-way streets. In order to reduce the number of fatalities caused by traffic accidents, the mayor wants to convert as many streets as possible into one-way streets. You have been hired to perform this conversion, so that from each intersection, it is possible for a motorist to drive to all the other intersections following some route.

You will be given a list of streets (all two-way) of the city. Each street connects two intersections, and does not go through an intersection. At most four streets meet at each intersection, and there is at most one street connecting any pair of intersections. It is possible for an intersection to be the end point of only one street. You may assume that it is possible for a motorist to drive from each destination to any other destination when every street is a two-way street.

Input

The input consists of a number of cases. The first line of each case contains two integers n and m. The number of intersections is n ($2 \leq n \leq 1000$), and the number of streets is m. The next m lines contain the intersections incident to each of the m streets. The intersections are numbered from 1 to n, and each street is listed once. If the pair $i\ j$ is present, $j\ i$ will not be present. End of input is indicated by $n = m = 0$.

Output

For each case, print the case number (starting from 1) followed by a blank line. Next, print on separate lines each street as the pair $i\ j$ to indicate that the street has been assigned the direction going from intersection i to intersection j. For a street that cannot be converted into a one-way street, print both $i\ j$ and $j\ i$ on two different lines. The list of streets can be printed in any order. Terminate each case with a line containing a single '#' character.

Note: There may be many possible direction assignments satisfying the requirements. Any such assignment is acceptable.

Sample Input

Problem F: Parallel Deadlock

A common problem in parallel computing is establishing proper communication patterns so that processors do not deadlock while either waiting to receive messages from other processors, or waiting for the sending of messages to other processors to complete. That is, one processor will not complete sending a message until it is received by the destination processor. Likewise, a receive cannot complete until a message is actually sent.

There are two modes of communication: blocking and non-blocking. A blocking send will not complete until a matching receive is performed at the destination processor. Likewise, a blocking receive will not complete until the matching send is performed by the source processor. Non-blocking actions will "return" immediately (i.e., allow the program to continue), but will not actually complete until the matching action is performed at the target. The matching action of a send is a receive (either blocking or non-blocking), and similarly, the matching action of a receive is a send (either blocking or non-blocking).

At the start of each timestep, each processor that is not blocked starts to run its next instruction. Processors that execute blocking instructions become blocked. Messages can be received at the end of the timestep in which they are sent, but may need to wait several timesteps until the recipient performs a matching receive. If the recipient of a message is waiting to receive from the sender, then the message is received in the same timestep. Messages are received in the order that they are sent. If all of the actions for a particular blocking instruction complete at the end of the timestep, then the processor that ran the instruction will be unblocked before the next timestep.

A correct program will terminate only when all of its actions have completed. Pending non-blocking operations must be completed before a program can terminate.

Your program will take in a list of processors and actions (no more than 100 for each processor), and determine if each processor finishes its program. If a given processor does not finish, it must print out which other processors are preventing it from finishing.

Input

The first line will be a single positive integer that tells how many processors will be listed. For each processor there will be one line containing the name of the processor (a single capital letter) followed by a positive integer, N. The following N lines will contain the instructions that comprise the program for that processor.

An instruction is of the form "*Mode Action Target(s)*" where "*Mode*" can be "B" or "N", for blocking or non-blocking, respectively. "*Action*" can be "S" or "R", for send or receive, respectively. "*Target(s)*" will be one or more processor names to which the action is to be addressed. No processor will be listed twice and a processor will never attempt any sort of communication with itself . A send to multiple targets will not complete until matching receives

have been performed by all of the targets (and vice versa).

Output

Given that instruction 1 occurs at $t = 1$, your program will output at which timestep each processor finishes. If a processor does not finish, you must output which processor are preventing that processor from finishing. Processors should be listed in alphabetical order, both for the list of processors and the sets of processors that prevent a processor from finishing. The list of processors preventing termination should list processors at most once and separate multiple processors with "and".

Sample Input

```
4
I 5
B S B P C
N S B P C
N R B
B R P
B R C
B 2
B R I
B S I
P 3
N S I
N R I
B R I
C 4
N S I
B R I
B S P
B R I
```

Sample Output

```
B finishes at t=4
C never finishes because of P
I never finishes because of B and C
P finishes at t=5
```

Notice how C's final blocking receive would be matched by a send on I if both instructions were executed. However, it never gets executed because it is stuck in the blocking send to P (that has no matching receive on P), therefore causing deadlock on I.

Problem G: DNA Sorting

One measure of "unsortedness" in a sequence is the number of pairs of entries that are out of order with respect to each other. For instance, in the letter sequence "DAABEC", this measure is 5, since D is greater than four letters to its right and E is greater than one letter to its right. This measure is called the number of inversions in the sequence. The sequence "AACEDGG" has only one inversion (E and D)—it is nearly sorted—while the sequence "ZWQM" has 6 inversions (it is as unsorted as can be—exactly the reverse of sorted).

You are responsible for cataloguing a sequence of DNA strings (sequences containing only the four letters A, C, G, and T). However, you want to catalog them, not in alphabetical order, but rather in order of "sortedness", from "most sorted" to "least sorted". All the strings are of the same length.

Input

The first line contains two integers: a positive integer n ($0 < n \leq 50$) giving the length of the strings; and a positive integer m ($0 < m \leq 100$) giving the number of strings. These are followed by m lines, each containing a string of length n.

Output

Output the list of input strings, arranged from "most sorted" to "least sorted". Since two strings can be equally sorted, there may be several different correct outputs.

Sample Input

```
10 6
AACATGAAGG
TTTTGGCCAA
TTTGGCCAAA
GATCAGATTT
CCCGGGGGGA
ATCGATGCAT
```

Sample Output

```
CCCGGGGGGA
AACATGAAGG
GATCAGATTT
ATCGATGCAT
TTTTGGCCAA
TTTGGCCAAA
```

Problem H: Numbers That Count

"Kronecker's Knumbers" is a little company that manufactures plastic digits for use in signs (theater marquees, gas station price displays, and so on). The owner and sole employee, Klyde Kronecker, keeps track of how many digits of each type he has used by maintaining an inventory book. For instance, if he has just made a sign containing the telephone number "5553141", he'll write down the number "5553141" in one column of his book, and in the next column he'll list how many of each digit he used: two 1s, one 3, one 4, and three 5s. (Digits that don't get used don't appear in the inventory.) He writes the inventory in condensed form, like this: "21131435".

The other day, Klyde filled an order for the number 31123314 and was amazed to discover that the inventory of this number is the same as the number—it has three 1s, one 2, three 3s, and one 4! He calls this an example of a "self-inventorying number", and now he wants to find out which numbers are self-inventorying, or lead to a self-inventorying number through iterated application of the inventorying operation described below. You have been hired to help him in his investigations.

Given any non-negative integer n, its inventory is another integer consisting of a concatenation of integers $c_1 d_1 c_2 d_2 \ldots c_k d_k$, where each c_i and d_i is an unsigned integer, every c_i is positive, the d_i satisfy $0 \leq d_1 < d_2 < \ldots < d_k \leq 9$, and, for each digit d that appears anywhere in n, d equals d_i for some i and d occurs exactly c_i times in the decimal representation of n. For instance, to compute the inventory of 5553141 we set $c_1 = 2$, $d_1 = 1$, $c_2 = 1$, $d_2 = 3$, etc., giving 21131435. The number 1000000000000 has inventory 12011 ("twelve 0s, one 1").

An integer n is called self-inventorying if n equals its inventory. It is called self-inventorying after j steps ($j \geq 1$) if j is the smallest number such that the value of the j-th iterative application of the inventory function is self-inventorying. For instance, 21221314 is self-inventorying after 2 steps, since the inventory of 21221314 is 31321314, the inventory of 31321314 is 31123314, and 31123314 is self-inventorying.

Finally, n enters an inventory loop of length k ($k \geq 2$) if k is the smallest number such that for some integer j ($j \geq 0$), the value of the j-th iterative application of the inventory function is the same as the value of the $(j+k)$-th iterative application. For instance, 314213241519 enters an inventory loop of length 2, since the inventory of 314213241519 is 412223241519 and the inventory of 412223241519 is 314213241519, the original number (we have $j = 0$ in this case).

Write a program that will read a sequence of non-negative integers and, for each input value, state whether it is self-inventorying, self-inventorying after j steps, enters an inventory loop of length k, or has none of these properties after 15 iterative applications of the inventory function.

Input

A sequence of non-negative integers, each having at most 80 digits, followed by the terminating

value -1. There are no extra leading zeros.

Output

For each non-negative input value n, output the appropriate choice from among the following messages (where n is the input value, j is a positive integer, and k is a positive integer greater than 1):

> n is self-inventorying
> n is self-inventorying after j steps
> n enters an inventory loop of length k
> n can not be classified after 15 iterations

Sample Input

```
22
31123314
314213241519
21221314
111222234459
-1
```

Sample Output

```
22 is self-inventorying
31123314 is self-inventorying
314213241519 enters an inventory loop of length 2
21221314 is self-inventorying after 2 steps
111222234459 enters an inventory loop of length 2
```
